

- Brainstormed and researched possibilities of how to complete the task.
- Analyse the image and break it down into sections. Plan which section will be in each file e.g. header.php, front page.php and footer.php
- Adding a custom font to a custom theme was something that was unfamiliar to me so I had to experiment a little with this.
- Creating the lines: At first I attempted to create 6 divs and give them borders on the right and left however I ran into an issue with the middle border where in the original design the line starts from the bottom and stops at the male models face. The issue was that my border line started from the top and I was having trouble figuring out how to make it start from the bottom. (Please view the middle line in the screenshot for reference)

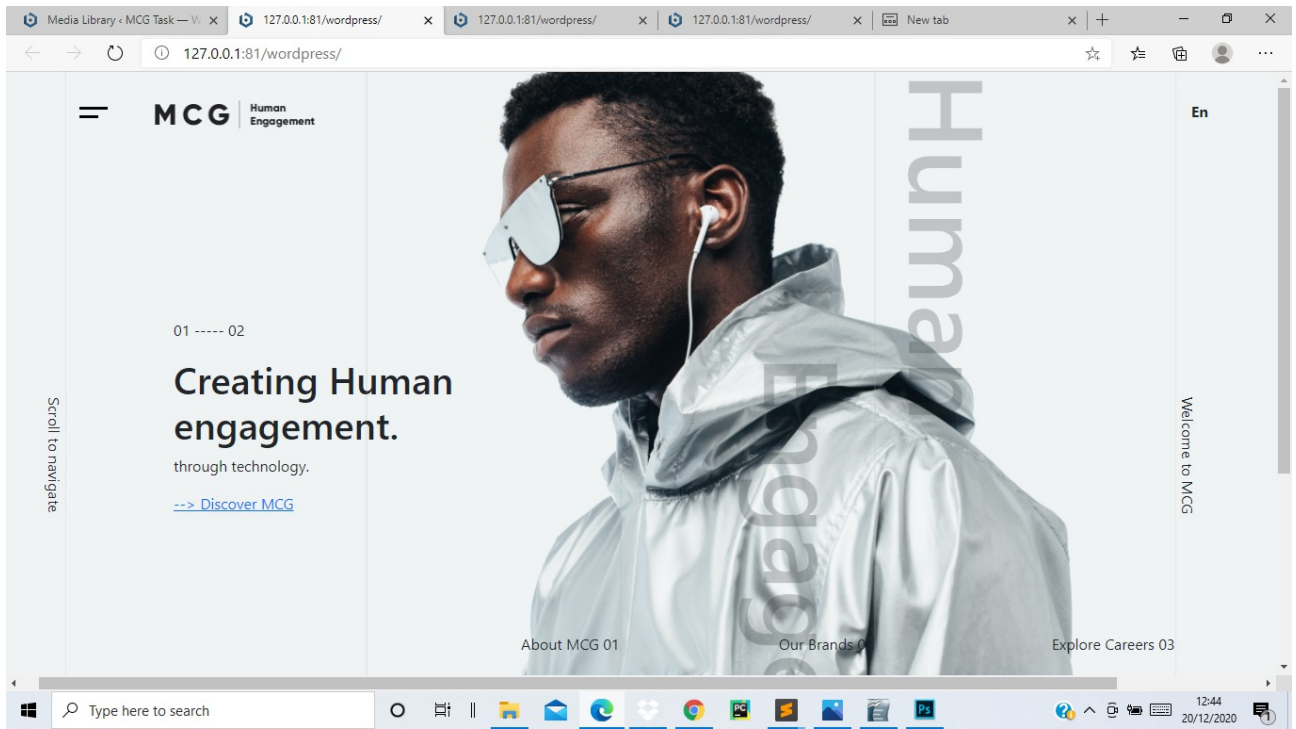

So I decided to use the same parameters of my div and recreate the lines using photoshop and add it to the background image. However once I opened photoshop and saw the outling of the original image, it gave me the idea to use two rows instead of phone.

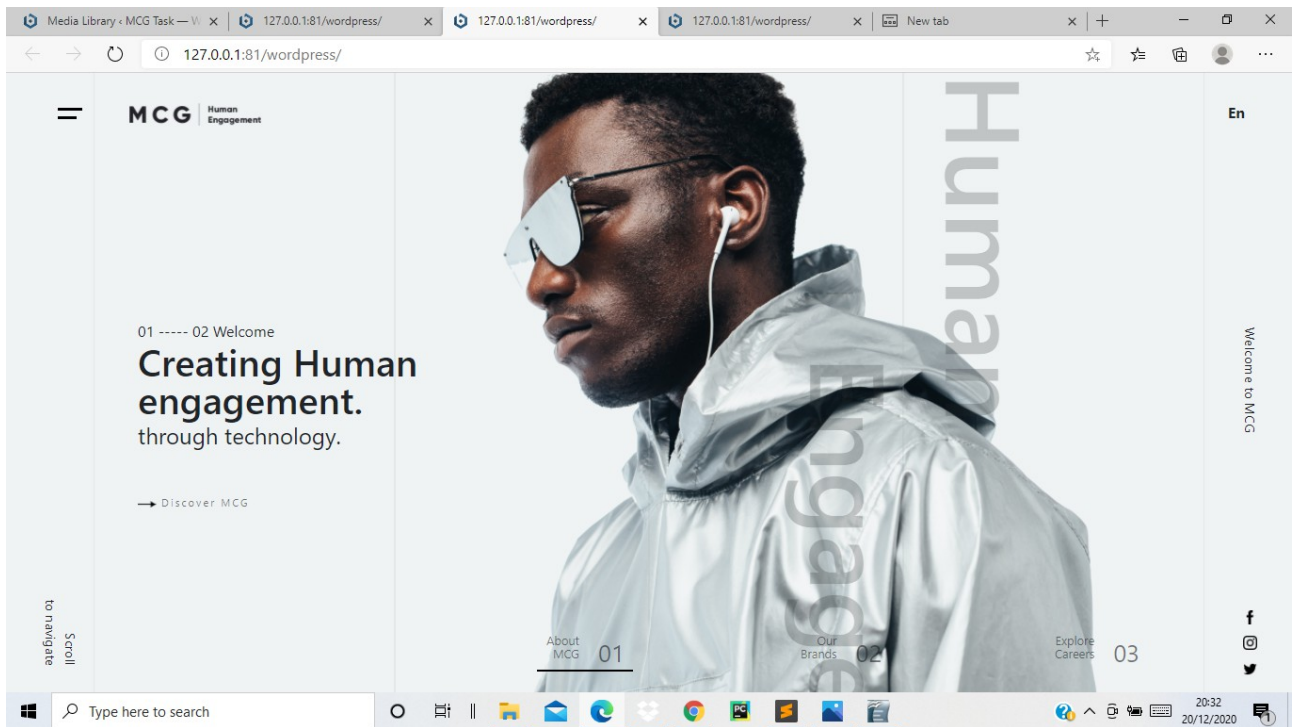

This way I could give the appearance of the border line starting from the bottom.

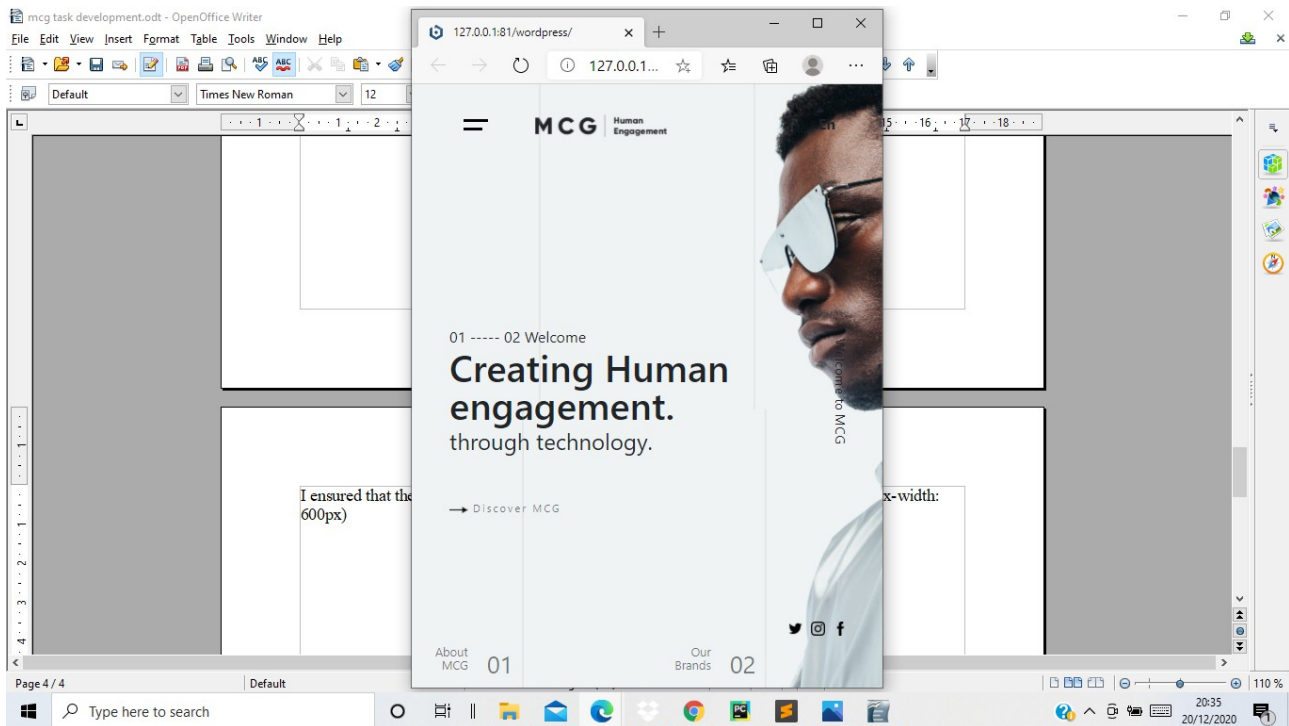

-To recreate the sideways text I will use the css property writing-mode: vertical-rl;

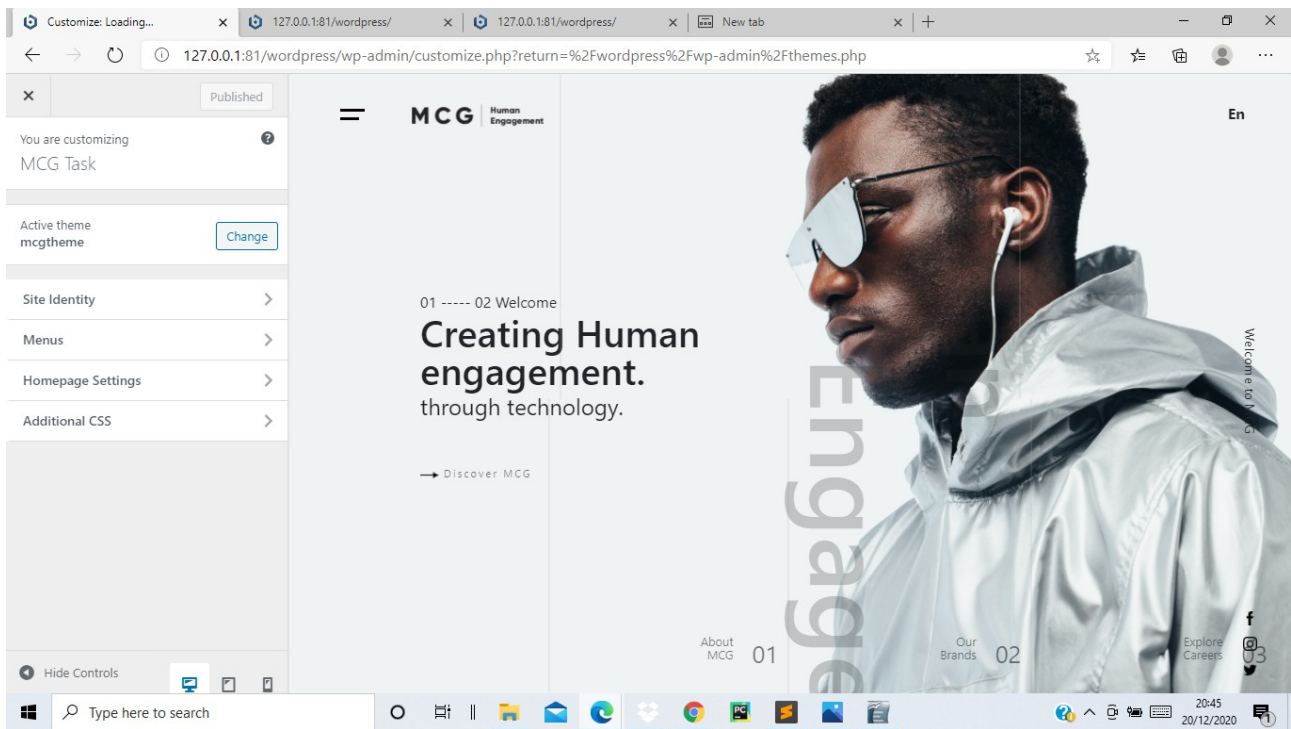

Using css hover I was able to add the same effect as the original design, making a line appear under the links at the bottom once a user hovers over them.

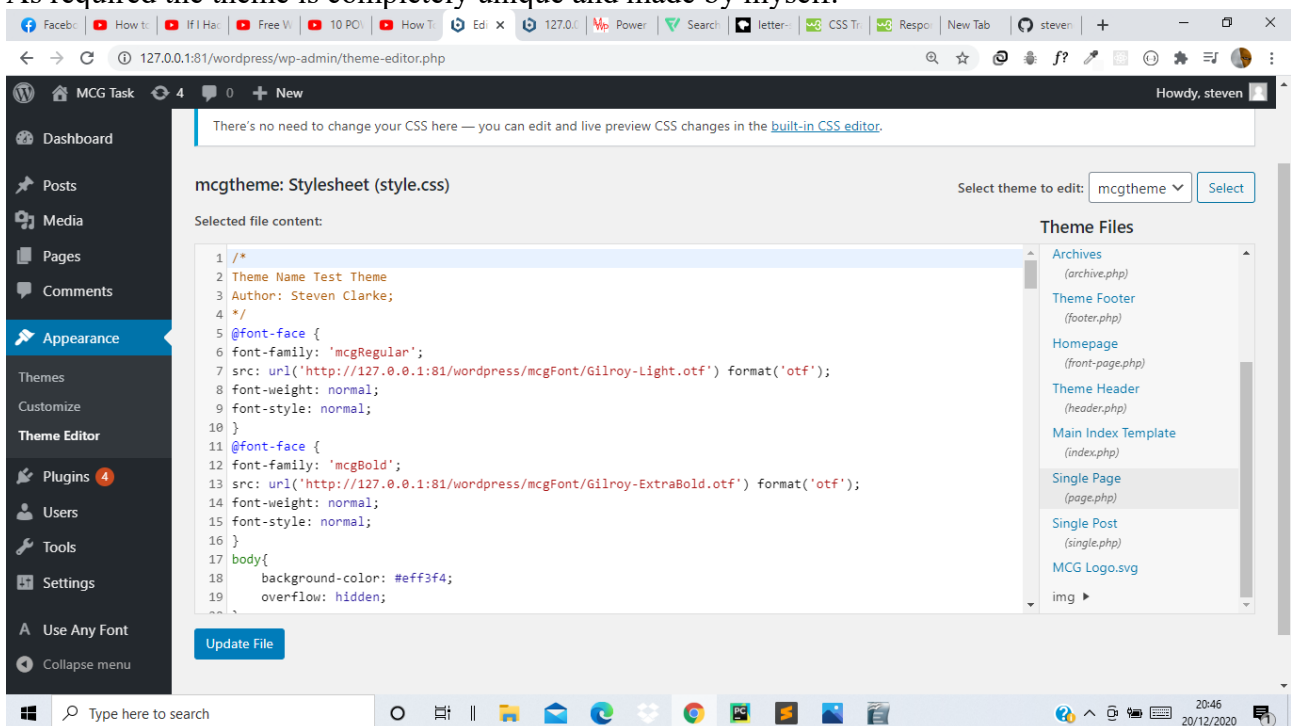

I ensured that the website was mobile responsive by using @media only screen and (max-width: 600px)

I was not able to import the same font as the design through my own Wordpress theme and still make the deadline of three days. After doing research many methods of achieving this was through paid plug-ins. I will continue to research this on my own to teach myself how to do it manually.

As required the theme is completely unique and made by myself.

Thank you for viewing the development of this project.
